Limits and Continuity

Limits

🌐 Limit 🌐 | Thomas' Calculus (2.2–2.6) 🌐

- **Limit** $\lim_{x \rightarrow c}$: the value of a function (or sequence) approaches as the input (or index) approaches some value (informal definition)
 - Limits are used to define **continuity** ↓, **derivatives** ↓, and **integrals** ↓

Limits of a Functions and Sequences

🌐 Limit of a function 🌐 | Limit of a sequence 🌐

- **Limit of a function**: a fundamental concept in calculus and analysis concerning the behavior L of a function near a particular input c , i.e.,

$$\lim_{x \rightarrow c} f(x) = L$$

- Reads as “ f of x tends to L as x tends to c ”
- ϵ, δ **Limit of function**: a formalized definition, wherein $f(x)$ is defined on an open interval, except possibly at c itself, leading to above definition, if and only if:
 - For every real measure of **closeness** $\epsilon > 0$, there exists a real **corresponding** $\delta > 0$, such that for all existing further approaches there exist a smaller ϵ , i.e.,

$$f : \mathbb{R} \rightarrow \mathbb{R}, c, L \in \mathbb{R} \Rightarrow \lim_{x \rightarrow c} f(x) = L$$

$$\forall \epsilon > 0 (\exists \delta > 0 : \forall x, 0 < |x - c| < \delta \Rightarrow |f(x) - L| < \epsilon)$$

- Functions do not have a limit when the function:
 - has a unit step, i.e., it “jumps” at a point;
 - is not bounded, i.e., it tends towards infinity;
 - or does not stay close to any single number, i.e., it oscillates too much.
- **Limit of a sequence**: the value that the terms of a sequence (x_n) “tends to” (and not to any other) as n approaches infinity (or some point), i.e.,

$$\lim_{n \rightarrow \infty} x_n = x$$

- ϵ **Limit of sequence**: for every measure of closeness ϵ , the sequence's term eventually converge to the limit, i.e.,

$$\forall \epsilon > 0 (\exists N \in \mathbb{N} (\forall n \in \mathbb{N} (n \geq N \Rightarrow |x_n - x| < \epsilon)))$$

- **Convergent**: when a limit of a sequence **exists**.
- **Divergent**: a sequence that **does not** converge.

Properties of Limits

📌 List of limits 📌 | Squeeze theorem 📌

- **Operations on a single known limit:** if $\lim_{x \rightarrow c} f(x) = L$ then:
 - $\lim_{x \rightarrow c} [f(x) \pm \alpha] = L \pm \alpha$
 - $\lim_{x \rightarrow c} \alpha f(x) = \alpha L$
 - $\lim_{x \rightarrow c} f(x)^{-1} = L^{-1}, L \neq 0$
 - $\lim_{x \rightarrow c} f(x)^n = L^n, n \in \mathbb{N}$
 - $\lim_{x \rightarrow c} f(x)^{n^{-1}} = L^{n^{-1}}, n \in \mathbb{N}, \text{ if } n \in \mathbb{N}_e \Rightarrow L > 0$
- **Operations on two known limits:** if $\lim_{x \rightarrow c} f(x) = L_1$ and $\lim_{x \rightarrow c} g(x) = L_2$
 - $\lim_{x \rightarrow c} [f(x) \pm g(x)] = L_1 \pm L_2$
 - $\lim_{x \rightarrow c} [f(x)g(x)] = L_1 L_2$
 - $\lim_{x \rightarrow c} f(x)g(x)^{-1} = L_1 L_2^{-1}$
- **Squeeze theorem:** used to confirm the limit of a function via comparison with two other functions whose limits are easily known or computed.
 - Let I be an interval having the point a as a limit point.
 - Let g, f , and h , be functions defined on I , except possibly at a itself.
 - Suppose that $\forall x \in I \wedge x \neq a \Rightarrow g(x) \leq f(x) \leq h(x)$
 - And suppose that $\lim_{x \rightarrow a} g(x) = \lim_{x \rightarrow a} h(x) = L$
 - Then, $\lim_{x \rightarrow a} f(x) = L$
 - Essentially, the hard to compute limit of the “middle function” is found by finding two other easy functions that “squeeze” the middle function at that point.
